INTRODUCTION

Nasal septum is considered a major structure for the nasal stability and functions. 1 Septal deviations are the most common cause of nasal obstruction. 2 Nasal septoplasty is a common surgical intervention, directed to improve nasal breathing Karlsson TR et al. 3 and sleep disturbances. 4 Approaches for correcting nasal septal abnormalities have experienced various changes since their inception, ranging from extreme septal resection to the retention of the septal structure and nasal mucosa. Septal abnormalities are frequently linked to lateral wall disorders or are the cause of them. Epistaxis, sinusitis, obstructive sleep apnea, and migraines have all been linked to a severely deviated nasal septum due to contact with lateral nasal wall components. 5 As a result, rectification of septal abnormalities is inextricably linked to the therapy of lateral wall problems. Endoscopic septoplasty can thus be used to address symptomatic abnormalities as well as to improve intraoperative surgical access to lateral nasal wall procedures (e.g., dacryocystorhinostomy, functional endoscopic sinus surgery). 6 Endoscopic septoplasty is a minimally invasive treatment for correcting DNS that was created as an alternative to standard submucosal excision. By confining the excision to the area of deviation in the affected area, the exceptional visualization of this method is thought to reduce morbidity and postoperative edema. 7

The aim of this work is to evaluate the effectiveness of the endoscopic septoplasty for correction of different types of septal deformity (deviation spur)
compared to endoscopic assisted conventional septoplasty.

PATIENTS AND METHODS

This prospective study was conducted on 60 patients of both sexes, who attached to the outpatient E.N.T clinic at Bab El Sharaya (Sayed Galal) Hospital from April of 2021 to March of 2022. All the patients suffering from nasal obstruction due to a significant septal deviation. All the study groups signed informed consents before surgery.

Inclusion criteria:
Age of patients range from 20 to 50 years old. Patients having different type of nasal septal deformity (deviation e.g. (c shaped – s shaped) - spur). patients presented with or without turbinate hypertrophy.

Exclusion criteria:
Inflammatory :- chronic or fungal rhinosinusites
Allergic nasal polyposis – antrochoanal polyp.
Neoplastic:- Inverted papilloma – squamous cell carcinoma.
Certain types of septal deviation e.g. dislocation, impaction.

Patients with associated co-morbidity (diabetes mellitus, hepatitis, renal disorders, hypertension, cardiac diseases, bleeding disorder, anemia (Hb less than 10 gm %), malnutrition).

All patients were subjected to: Careful history taking; Personal history : name ,age, sex ,occupation and residence.

Complaint and history of present illness regarding the nasal obstruction which was the main complaint of all patients with emphasis on onset, course, and duration of the nasal obstruction, the side of the obstruction, postnasal discharge, epistaxis and hyposmia.

Past history of using nasal decongestant drops or any other medical treatment and its effect.

Examination: Meticulous preoperative examination was done by anterior rhinoscopy. Nasal patency examination and diagnostic nasal endoscopy for all patients was conducted to meticulously assess the type and severity of the septal deviation. CT scans of the paranasal sinuses was done only when chronic sinusitis was suspected.

Investigations: Pre-operative routine investigations as complete blood count, bleeding time, coagulation time, prothrombin time, partial prothrombin time, random blood sugar, liver enzyme, serum creatinine, ECG, and chest X-ray were done.

The patients were randomly distributed into two groups: Group A 30 patients underwent totally endoscopic septoplasty and Group B 30 patients underwent conventional septoplasty assisted by endoscope.

Both procedures were carried out under general anaesthetic with auffed endotracheal tube in order to avoid blood aspiration or swallowing. At the start of the procedure, a five-minute pack soaked in adrenaline in saline solution (1: 200,000) was introduced into the nostril. The patients were positioned supine on the surgical table, with the head end lifted. both nasal cavities were packed using merocel packs at the end of operation in both techniques.

Technique of totally endoscopic septoplasty using the endoscope, submucosal infiltration of the nasal septum was done. An incision was performed directly on deviated part then a mucoperichondrial flap was dissected at the proper cleavage plane to minimize bleeding, using a Cottle elevator in the right hand and endoscope in the left hand. The septal cartilage was then incised posterior to the mucosal incision. The dissection of the contralateral mucoperichondrial flap was then performed. In cases of spur only, the incision was done directly over the spur using a sickle knife under endoscopic vision especially for posterior spurs.

The patients were randomly distributed into two groups: Group A 30 patients underwent totally endoscopic septoplasty and Group B 30 patients underwent conventional septoplasty assisted by endoscope.

Both procedures were carried out under general anaesthetic with a cuffed endotracheal tube in order to avoid blood aspiration or swallowing. At the start of the procedure, a five-minute pack soaked in adrenaline in saline solution (1: 200,000) was introduced into the nostril. The patients were positioned supine on the surgical table, with the head end lifted. Both nasal cavities were packed using merocel packs at the end of operation in both techniques.

Technique of totally endoscopic septoplasty using the endoscope, submucosal infiltration of the nasal septum was done. An incision was performed directly on deviated part then a mucoperichondrial flap was dissected at the proper cleavage plane to minimize bleeding, using a Cottle elevator in the right hand and endoscope in the left hand. The septal cartilage was then incised posterior to the mucosal incision. The dissection of the contralateral mucoperichondrial flap was then performed. In cases of spur only, the incision was done directly over the spur using a sickle knife under endoscopic vision especially for posterior spurs.
Technique of conventional septoplasty assisted by endoscope:

The conventional approach involves headlight illumination and visualization with nasal speculum. After injection, a Killian incision was made using a No. 15 blade. The incision was performed on the side of the deviation. Then the submucosal flaps were elevated, and the deviated segment was removed. In the end of operation we used 0 degree 4 mm endoscope to observe and remove any remnants of deviated nasal septum.

Postoperative care: Patients were kept under observation in the hospital for 24 for any sign of nasal bleeding. Antibiotics and oral anti-inflammatory were prescribed for all cases. After removal of nasal packs, patients were discharged and were kept on a regimen of alkaline nasal douche for one month. The nasal splint, if used, was removed after one week.

Postoperative evaluation: All patients were evaluated, once weekly for the first month then every 2 weeks for 3 months, then monthly till 6 months, regarding the nasal obstruction whether improved or not, and the degree of the improvement (no, mild, moderate, severe), also, the accompanying symptoms as a headache, snoring, postnasal discharge, epistaxis and hyposmia, whether disappeared or still persistent. Patients were checked out for any complications such as epistaxis, or any new symptoms that were not present preoperatively.

Types of the septal deformity showed no statistically significant difference between both groups, (P=0.196). In group A: 9 (30%) patients had c shaped deviated septum, whereas 9 (30%) patients had an isolated spur deviation, and 9 (30%) patients had c shaped septal deviation. In group B: 12 (40%) patients had a deviated septum, whereas 12 (40%) patients had an isolated spur deviation, and 9 (30%) patients had an isolated spur deviation. Likewise, among 30 patients (group A) who underwent endoscopic septoplasty, 17 (56.7%) were males and 13 (43.3%) were female patients. Among 30 patients (group B) who underwent conventional septoplasty, 12 (40%) were males and 18 (60.0%) were female patients.

Statistical analysis

Prior to statistical analysis, the data were checked for normality using the Kolmogorov-Smirnov test. Continuous variables were defined by range, mean, and standard deviation, while categorical variables were described by number and percent (N, percent) (SD). The chi-square test and Fisher exact test were used to compare categorical variables, while the t-test was used to analyze continuous variables. Statistical significance was defined as a two-tailed p 0.05. The IBM SPSS 20.0 program was used to conduct all of the analyses.

RESULTS

There was no statistically significant difference in age and sex of both groups. (P-value was 0.379 & 0.196 respectively). Mean age of group A was 29.77 ± 6.58 years with range among 20 and 44 years and Mean age of group B was 31.27 ± 6.51 years with range among 20 and 50 years. 30 patients (group A) who underwent endoscopic septoplasty, 17 (56.7%) were males and 13 (43.3%) were female patients. Likewise, among 30 patients (group B) who underwent conventional septoplasty, 12 (40%) were males and 18 (60.0%) were female patients.
There is no statistically significant in pre-operative assessment of nasal manifestations in both groups.

Table 4: Post-operative complications in both groups.

Regarding post-operative complications in both groups there is not statistically significant between both groups.

DISCUSSION

In this study, there were no significant differences detected among both groups regarding demographic data such as age and sex. Also, both groups showed insignificant differences regarding types of septal deformities. The most common affected group was of the younger age groups. This was in concordance with the study of Rao JJ.

Regarding the duration of conventional and endoscopic septoplasty. Using the endoscope, the incision was made on the spur itself which markedly reduced the extent of subperichondrial dissection. This resulted in an apparent reduction in the duration of the procedure compared to the conventional septoplasty with a statistically significant difference (p 0.001). Supporting this study results, Aiyer et al. reported that, regarding cases of isolated spur or limited deviation in the nasal septum, the duration of endoscopic septoplasty was relatively shorter than traditional septoplasty. On the other side, Richtsmeier et al. reported that the average time of limited endoscopic septoplasty was 12min. Comparatively, the time required for a traditional septoplasty was nearly threefold (35min). We found an insignificant difference between both groups in the intraoperative flap tear (p 0.136). Similar to these results were the results of Kaushik et al. who reported an intraoperative flap tear in 3 cases (10%) in the conventional group and 2 cases (6.67%) in the endoscopic group with an insignificant difference between both groups. On the contrary, Suligavi et al. reported flap tear in 18 out of 50 cases (36%) in the conventional group and 10 out of 50 cases (20%) in the endoscopic group with a significant difference between both groups. To avoid synchiae formation following the intraoperative flap tears, septal splints were used in this study in all cases . Jung et al. support this study regarding that splint should be a routine step in septal surgery. On the contrary, according to Tang et al., placement of splints is unnecessary and should not be considered as a rule.

The difference of the endoscopic group as compared to the conventional group was statistically insignificant regarding early post-operative findings (p 0.166). Similar results were Obtained by Kaushik et al. who reported more epistaxis cases in the conventional group than the endoscopic group with a statistically insignificant variance. On the other hand, Suligavi et al. reported a statistically significant difference between the conventional group [13 cases (26%)] and the endoscopic group [7 cases (14%)]. In this study, the differences were statistically insignificant in nasal synchiae, nasal crustations, septal hematoma or septal perforation (p-value 0.228, 0.228, 0.313, & 0.150 respectively). Results of this study agree with Bothra et al. who did not detect statistically significant differences in the reported immediate post-operative complications. Regarding this study, after 3 months postoperative, 2 patients (6.7%) of group A had a persistent posterior deviation, but neither persistent anterior nor spur deviations were present. On the contrary, 4 patients (13.3%) of group B suffered a persistent posterior deviation, but no patients had a persistent anterior deviation or spur deviations. (P-value 0.389 & 0.150 respectively). No nasal synchiae, nasal crustations nor septal hematoma was recorded in both groups. While, 2 patients (6.7%) of group B had anterior septal perforation(fig.3) , but no patient had a septal perforation in group A. Difference between both
group was statistically insignificant. The results of this study agree with the results of Kaushik et al. regarding persistent posterior and spur deviations who reported statistically insignificant differences between both groups. In our study, the postoperative improvement of nasal manifestations after 3 months such as Nasal obstruction, Headache, post nasal discharge, epistaxis, smell disorders and ear complaint shows no statistically differences between both groups. The results of this study agree with the results of Gupta et al. However the chief complaint of the patients in our study was nasal obstruction in group A and 4 (13.3%) patients in group B. There is no statistically difference between both groups (p value 0.389). In a similar study done by Sathyaki et al. conducted on 50 patients with nasal obstruction, 46 of the 50 patients were relieved of nasal obstruction of which 22 of the 25 patients belonged to conventional and 24 of the 25 patients belonged to endoscopic septoplasty group. Use of an endoscope during the performance of the conventional septoplasty to assess the result of the procedure and correction of the defect not visualized by the naked eye is advantageous especially in relief of symptoms of nasal obstruction and headache.

CONCLUSION

In cases with isolated septal spur or posterior deviations the totally endoscopic septoplasty is preferred because the incision was done directly over the spur and therefore it requires shorter time than conventional methods with less blood loss and better visualization. While in cases with anterior deviation conventional septoplasty assisted by endoscope is preferred because we can use both hands and allow binocular vision.

Conflict of interest: none
